Abstract

Given the limited success of past and current conservation efforts, an alternative approach is to preserve tissues and genomes of targeted organisms in cryobanks to make them accessible for future generations. Our pilot preservation project aimed to obtain, expertly identify, and permanently preserve a quarter of the known spider species diversity shared between Slovenia and Switzerland, estimated at 275 species. We here report on the faunistic part of this project, which resulted in 324 species (227 in Slovenia, 143 in Switzerland) for which identification was reasonably established. This material is now preserved in cryobanks, is being processed for DNA barcoding, and is available for genomic studies.

Introduction

Today, the importance of understanding and conserving biodiversity is undisputed. However, climate changes, urbanization, deforestation and pollution all critically affect most of the planet's ecosystems, which consequently are changing too rapidly for organisms to adapt to (Dornelas et al. 2013). Biodiversity exploration, preservation and conservation are thus among the main challenges for humanity, yet our current efforts seem not to be effective enough (Hoban and Vernesi 2012). Because of that, several new approaches for biodiversity conservation recently emerged, among which is cryo-preservation. As an example, Smithsonian Institution recently launched the Global Genome Initiative (<http://www.mnh.si.edu/ggi/>), whose goal is precisely to preserve tissues and genomes of many targeted organisms to make these materials accessible for future generations. As a pilot preservation project funded by the Swiss Contribution to the enlarged EU we partnered with the Global Genome Initiative to conduct a study that aimed to permanently preserve a large proportion of European spider fauna by deep-freezing their tissues and DNA. With over 43 thousand known species (<http://research.amnh.org/iz/spiders/catalog/INTRO1.html>), the hyperdiverse order Araneae ranks seventh among animal orders (Coddington and Levi 1991). As obligate predators, spiders also play prominent ecological roles in all terrestrial ecosystems, and are important biocontrol agents (Foelix 2010). Biorepositing a portion of a known spider fauna, thus, may be an important step in conservation. However, because species identification in spiders is not straightforward, the goal here was to produce expertly identified specimens for preservation, for genomic DNA extraction and for DNA barcoding (Hebert et al. 2003). We targeted a quarter of the known spider diversity shared between Slovenia and Switzerland, which estimated from the available checklists (Maurer and Hänggi 1990, http://www.arages.de/checklist.html#2004_Araneae, own unpublished data for Slovenia) may number roughly 275 species. To do that, we conducted field work at over 100 localities throughout Slovenia and Switzerland. Here, we report on the faunistic data from this project, resulting in well over the targeted numbers of expertly identified taxa.

Materials and methods

In 2010-2012, we collected spiders at 74 and 33 localities in Slovenia and Switzerland, respectively (Fig. 1). In order to increase the number of targeted spider species, we sampled in a wide variety of habitats ranging from mountain regions, lowland grasslands and forests, to coastal regions and caves. To sample in diverse microhabitats, we used several sampling methods, i.e. hand-collecting, beating vegetation, using sweep nets and sifting leaf litter. We also sampled using a gasoline powered leaf blower with a sock-like filter made out of rough textile to intercept material. Captured spiders were immediately fixed in absolute ethanol and samples were kept in a cooler or refrigerator. In the laboratory, we discarded all juveniles as is standard in quantitative sampling (Coddington et al. 1996, Coddington et al. 2009, Scharff et al. 2003). We expertly identified adults to

species level where possible. Identifications were mainly done using the online European spider key (www.araneae.unibe.ch), but we also consulted primary literature as needed. A representative subsample of all identified species was set aside for DNA extraction for DNA barcoding purposes (these results will be reported elsewhere). The voucher specimens resulting from this study will be deposited in the collections of the National Museum of Natural History, Smithsonian Institution, USA, and in Naturhistorisches Museum Bern, Switzerland, but the bulk of the material remains in the study collection of the EZ lab at the Institute of Biology, Scientific Research Centre, Slovenian Academy of Sciences and Arts, Ljubljana, Slovenia (<http://ezlab.zrc-sazu.si/>).

Analysis

Altogether, we identified 1596 adult individuals, belonging to 324 species, 183 genera and 33 spider families. From the 76 localities in Slovenia, we recorded 227 species belonging to 144 genera and 31 families. From the 33 localities in Switzerland, we recorded 143 species belonging to 89 genera and 18 families. The number of unique species was 181 and 97 for Slovenia and Switzerland, respectively. As an indication of rare species in

our survey, singletons (those species represented on the list with a single individual (Coddington et al. 1996, Coddington et al. 2009) represented 38,27% (124 species).

Discussion

Faunistic research has recently been neglected in most scientific outlets. Yet, faunistic studies contain crucial base line data urgently needed for ecological work, and particularly for meaningful conservation decisions. We see no reason for taxonomic experts of particular clade, such as spiders, not to offer such hard produced data to the public, particularly if these researchers consulted an array of literature sources to back up the species identifications. Our survey spanning two central European countries, Slovenia and Switzerland, is larger in scope and in faunistic data compared with most temperate studies reported in the literature. A quick overview of the literature suggests that only one study of temperate spider fauna reports more than 300 species (Blick 2011), and an additional study reports on more than 275 species that we initially targeted in our study (Blick 1996, Blick 2009).

The main goals of our study was not to merely report on the species lists, nor to compare the lists between the two countries as the sampling was not structured qualitatively nor quantitatively. Rather, this report is the first step towards our larger efforts to process this freshly collected and expertly identified biological material further. Thus, our upcoming works will report on the inclusion of selected vouchers from this survey in permanent preservation facilities, both as tissue and as genome grade DNA. Furthermore, we intend to provide DNA barcode data for selected representatives of these reported faunas. Because the taxa reported here are expertly identified, upcoming DNA barcodes, once freely available on BOLD and GenBank databases, will facilitate species identification (Barrett and Hebert 2005).
